Parental Expectations Dictate Success

Parental expectations may dictate success or failure in a child's life. Parents must have expectations of children on the fundamental facts of child development.

For instance, parents can't expect an 18-month-old to keep all his food on the high chair tray or expect a three-year-old to always do everything he's told to do. It is equally absurd to expect a 6- or 8-year-old to keep a spotless, well-ordered bedroom.

Some children might be the average child will not. There are many ways to find out the basic facts. Many parents get together in small groups on a regular schedule to discuss their concerns and to learn from one another the various aspects of child development.

After considering the basic or general facts of child development, check your own expectations against these facts.

One way to accomplish this task is to teach yourself when you yell at or otherwise correct your child. Keep a small notepad handy and make a note about the incident.

At the end of the day, survey your list and notice those things the child did that you felt you had to change or would him about.

After a week or so, you should have a clear idea of your expectations.

Now check them against the basic facts of child development and your own child's development.

With some creative thinking, you should be able to adjust, if necessary, your parental expectations.

Additional Promotion Urged For Rice At Field Day

Congressman Brooks Speaks At Beaumont Field Day

U.S. Rep. Jack B. Brooks has recommended to rice industry leaders that more efforts be made to convince and to sell people in other areas to "eat more rice."

"We natives of the rice country eat rice, and although projections indicate a good year for exports this should not divert from the great need to develop domestic consumption of our product," Brooks assured.

Brooks, of Beaumont, spoke at the 33rd Annual Rice Field Day at Texas A&M University's Agricultural Research and Extension Center located some 10 miles west of Beaumont.

Dr. Julian Craigie, resident director of research, said that more than 450 rice growers and representatives of businesses participated in the activities which included tours of research projects and farm equipment.

Much interest focused on an experimental long grain, semi-dwarf rice which Dr. Charles N. Bollich, rice breeder, said probably will be released in 1981 for widespread commercial acreage.

The rice is about 35 inches in maturity, compared with 44 to 48 inches of the traditional varieties. The short stalk will enhance chances of withstanding high winds, and other inclement weather.

Brooks, a veteran of 30 years as representative of the 9th District of Texas, added, "Over the long haul our national interest is best served by making sure that the small farmer is not driven out by either giant agribusiness corporations, or the unfair trading practices of foreign nations."

County Agent's NOTEBOOK

(By Leroy J. Hajdik, County Extension Agent, Colorado County)

Management Of Stored Grain Pests

Small grains have been stored and soon corn and grain sorghum will be placed in farm storage facilities. The management of the grain while in storage will determine the amount of insect damage that occurs.

One of the first requirements for proper grain storage is the use of adequate facilities. A good facility should exclude all outside moisture, be easily accessible for inspection and fumigation of the grain. Bins in which grain is stored should be kept clean before they are used. Bins should be thoroughly cleaned of all waste material and sprayed with a residual spray. Old grain, trash, or other debris furnish excellent living quarters for insects.

Methoxychlor and malathion can be used to treat storage bins. Only material that has a label stating that it can be used for bin treatment should be purchased. Storage bins should be cleaned and treated four to six weeks before grain is placed in them.

The condition of the grain when it is placed in storage influences insect infestations. Harvesting grain too wet provides an environment for insects and causes an added cost because the grain must be dried to 12% moisture or less before being put into the bin. Grain containing more moisture attracts insects, promotes mold growth and may induce heating.

Cracked grain attracts insects and aids in their development. Wheat should be harvested as dry as possible with the combine adjusted properly to eliminate weed seeds and keep cracking of kernels at a minimum.

Malathion, the only approved readily available grain protectant, can be applied as a spray or dust to limit insect development in farm stored grain. Mix sprays and use according to label directions. Sprays can be applied with hand sprayers or sprayers operated from motor-driven pumps. It can also be applied by letting it drip into the grain at a control rate as it enters the auger.

After grain has been put into the bin, apply a surface treatment to prevent insects from entering the grain or feeding on the surface. Premium grade malathion can be used as a surface treatment. A bacterium, *Bacillus Thuringiensis*, can be used to control the Indian meal moth, which has shown some resistance to malathion, but this material will not control weevils or other beetles. The surface treatment should be repeated if insect activity is detected or if the surface is disturbed.

To keep grain in good condition it should be inspected monthly during cooler months and twice each month during the summer and early fall. A grain probe is needed to inspect for insects. A temperature sensor cable installed in the bin or a thermometer on the end of a stick is needed to keep track of the temperature of the grain.
